I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

Dear Florida Department of Environmental Protection,

I'm writing as a Florida voter who had the chance to visit the USF St Pete Marine Science Lab last week, and was amazed at the committed young scientists so completely dedicated to taking care of our Florida waterways and coastlines.

So many of these scientists are absolutely focused on studying harmful algae blooms and working hard to find out the causes. Both students and teachers will gladly explain to you exactly how algae blooms affect the water all around us.

One cause that's clearly identified is cyanotoxins. So I urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

**Date:** Monday, November 18, 2019 1:24:21 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Robert Schicker

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. **Date:** Monday, November 18, 2019 2:07:34 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Kimberly Rutledge

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Gloria Diggle

---

Dear Florida Department of Environmental Protection,

All of the environmental protections that have been rolled back need to be replaced and strengthened! We need to be smarter about preserving Florida's natural legacy. It's why tourists come here and ultimately why we don't pay state income tax!

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Karin Braunsberger

**Date:** Monday, November 18, 2019 3:19:36 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

In the past, Florida has been the national leader in developing biomonitoring criteria for aquatic invertebrates. This review is an opportunity for the state to reclaim its former preeminence in protecting state waters.

I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows, and levels to rising temperatures and changes in precipitation fueled by climate change. I have been a resident of Florida for the majority of my life. I never remember the immensity red tide has become and the prevalence of flesh-eating bacteria. I know these things have always been present in our waters but, not to the extent they are today. The amount of fertilizer and other toxic substances allowed to run into our waters is out of control and I believe contributes to the state our coastal waters are in today. Let's get busy and clean up our waterways. Set up fish sanctuaries and ban shark finning so we can once again become the great fishing destination Florida once was.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

**Date:** Monday, November 18, 2019 3:48:29 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Julie Stuckey

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Mary Walls

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation which can lead to long, looming medical conditions for our future and great fish and coral die off!

We need clean water, air and food. And our great great grandchildren will need them, too. This planet is our nurturing mother who gives us natural resources and these are running out! What do you replace it with, dry deserts, oceans of salt water? We must bring back our conservation programs or change them to not allow for large corporations to be greedy. They should not be allowed to do whatever they want and they should be TAXED. Why aren't they? Because we want to bring big business back to America? ... But this is not the solution. Politicians need to get back to work and think this out. This is why you were elected, to do your jobs! So do it.

Science:

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

**Date:** Monday, November 18, 2019 11:36:57 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Carolina Patino

**Date:** Monday, November 18, 2019 10:08:43 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Mary Lynn Smith

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

**Date:** Monday, November 18, 2019 9:35:43 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

V V

People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Elizabeth Watts

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Diane Riley  
Palm Beach Gardens, FL 33410

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Victoria Kilroy

**Date:** Monday, November 18, 2019 7:58:54 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Rachel Wynnberry

**Date:** Monday, November 18, 2019 6:56:36 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Jennifer Graham

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Carolyn Warner

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. Algal blooms produce cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

I am particularly concerned about BMAA produced by blue-green algal blooms.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

Dear Florida Department of Environmental Protection,

I'm urging you to establish strict, meaningful criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Janet Zinner  
Sarasota, FL 34239

They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

**Subject:** Please Establish Water-quality Criteria for Cyanotoxins  
**Date:** Monday, November 18, 2019 5:17:20 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. Harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing relevant criteria for cyanotoxins, the FDEP can finally set clear, accurate numeric baselines, formulated by scientists such as Dr. Larry Brand, for our state's recreational waters. Such guidelines would form the basis for future monitoring and help state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, with the highest concentrations below the water surface.

For all these reasons, I urge the state to adopt new, accurate criteria, using as a model the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin. This is the strongest, most comprehensive set of criteria put forth to date, far more so than the version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity to be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Alexandral Coleman

**Date:** Tuesday, November 19, 2019 10:16:54 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Vince Colaluca

People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Eren Anderson

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Molly Ganong

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

**Date:** Tuesday, November 19, 2019 5:57:35 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Ellie Joseph  
Tampa, FL 33625

The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. Dear Florida Department of Environmental Protection,

As a concerned Floridian in her sixties with health problems, I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know, algae blooms and the cyanotoxins they produce jeopardize the health of both people and wildlife. Your own family can be exposed to them through polluted water, contaminated seafood, skin exposure, and inhalation.

By establishing criteria for cyanotoxins, the Florida DEP would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become particularly dangerous. These criteria would also help address the factors contributing to these blooms — nutrient pollution; insufficient water velocities, flows and levels; rising temperatures and precipitation levels fueled by climate change; and so on.

Relying only on visual evidence of an algae bloom as a time for action is woefully inadequate. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all of these reasons, I urge the state to adopt new criteria -- and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. Harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
David Bernstein

**Date:** Wednesday, November 20, 2019 7:20:50 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

DO YOUR JOB FDEP, BEFORE WE'RE ALL DROWNING IN RED TIDE!!!

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Trikun Pongpitakyothin

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Solemi Hernandez

**Date:** Friday, November 22, 2019 6:06:51 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface. Scientists are finding that BMAA can be produced by every cyanobacteria. With a state that already has over half a million people with Alzheimer's, people need to be made aware of the dangers of this particular toxin and that it can be present in the water when there is no current bloom.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. This criteria needs to be utilized to close down beaches when the exposure risk is a threat to human health on the Gulf coast. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface. Tourists often have no idea there is an issue and residents are relying on only visual data, putting their health at risk.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

**Date:** Thursday, November 21, 2019 9:11:52 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Jason Hicks

Dear Florida Department of Environmental Protection,

Please PROTECT our waters.....for visitors and residents of Florida! We have this ONE natural resource that is so important to sustaining life. Please put priorities in the right place when it comes to protecting this natural resource.

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

All of the above are vital reasons to adopt the new criteria, but on a more personal note, my breathing is laboured and painful anywhere near the beaches in my district and thus the wonderful lifestyle we moved here for has been severely diminished. Please listen to our concerns.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

**Subject:** Please Establish Water-quality Criteria for Cyanotoxins  
**Date:** Friday, November 22, 2019 3:59:21 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Jill Sagona

The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Kris Cunningham

**Date:** Saturday, November 23, 2019 1:17:35 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. Dear Florida Department of Environmental Protection,

I live and work in Southwest Florida. I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Environmental Consultant Kaitlyn Sutton,

In 2019, Gov. DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governors appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

I firmly believe that Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period.

Dear Environmental Consultant Kaitlyn Sutton,

In 2019, Gov. DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governors appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

I firmly believe that Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period.

Regards,  
Terry Deegan  
3145 N Estates Pl  
St. Joseph, MI 49085

Dear Environmental Consultant Kaitlyn Sutton,

In 2019, Gov. DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governors appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

I firmly believe that Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period.

Regards,  
Alan Fritze

In 2019, Gov. DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governors appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

I firmly believe that Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period.

Dear Environmental Consultant Kaitlyn Sutton,

Please listen to the scientists that Gov. DeSantis appointed in 2019 to the Florida Blue-Green Algae Task Force and avoid a massive health care crisis in SW FL. They have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. Specifically, in their amended Draft Consensus Document, they include language to reflect the consensus of its members that the tolerated toxin levels need to be more restrictive than proposed.

I urgently ask that Florida put in place a protective harmful algae bloom toxins standard by which to measure public safety in the water. Without such targets, the public will be harmed and the government face a looming public health crisis from deadly diseases. I urge you to please adopt protective toxin standards in this rule-making period.

Dear Environmental Consultant Kaitlyn Sutton,

In 2019, Gov. DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governors appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

I firmly believe that Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period.

Regards,  
Robert Niebauer

Dear Environmental Consultant Kaitlyn Sutton,

I live in a senior community along the Caloosahatchee and near the Gulf. The issues with red tide and Cyanobacteria are impacting wildlife. Just last Saturday I was at Ding Darling and there were dead fish all along the mangroves. If wildlife is affected, people are at risk as well. All of this impacts our economy. Please read the following carefully and make positive steps for Florida and its residents.

In 2019, Gov. DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governors appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governors appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

I firmly believe that Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period.

Regards,

Dear Environmental Consultant Kaitlyn Sutton,

As a very frequent visitor to Florida, and Sanibel in particular, I am very concerned about water quality and availability. In 2019, Gov. DeSantis established the Florida Blue-Green Algae Task Force "to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state's natural resources and enforce its environmental laws." The scientists the Governors appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include "stronger" language to reflect the consensus of its members.

I firmly believe that Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period.

In 2019, Gov. DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governors appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

I firmly believe that Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period.

Regards,

**Subject:** Please protect us and Establish Water-quality Criteria for Cyanotoxins  
**Date:** Monday, November 18, 2019 12:24:51 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Mary Lane

Dear Environmental Consultant Kaitlyn Sutton,

Florida's allure for residents and tourists alike centers around water recreation. I urge DEP to lead the nation on protecting public health by setting protective recreational exposure standards to prevent mounting human health issues alongside an ecological crisis.

The intensity and expanse of blue-green algae we experienced in the summer of 2018 proved to us that ingestion is not the only mode of exposure. The EPA's final recommendations do not account for the additional modes of exposure by air, dermal contact and consumption of contaminated seafood - so lower, more protective levels should be set by the state while research continues to study the health effects. I urge you not to wait to protect the public.

---

Dear Environmental Consultant Kaitlyn Sutton,

Florida's allure for residents and tourists alike centers around water recreation. I urge DEP to lead the nation on protecting public health by setting protective recreational exposure standards to prevent mounting human health issues alongside an ecological crisis.

The intensity and expanse of blue-green algae we experienced in the summer of 2018 proved to us that ingestion is not the only mode of exposure. The EPA's final recommendations do not account for the additional modes of exposure by air, dermal contact and consumption of contaminated seafood - so lower, more protective levels should be set by the state while research continues to study the health effects. I urge you not to wait to protect the public.

Regards,  
Carolyn Ruff

The intensity and expanse of blue-green algae we experienced in the summer of 2018 proved to us that ingestion is not the only mode of exposure. The EPA's final recommendations do not account for the additional modes of exposure by air, dermal contact and consumption of contaminated seafood - so lower, more protective levels should be set by the state while research continues to study the health effects. I urge you not to wait to protect the public.

Dear Environmental Consultant Kaitlyn Sutton,

Florida's allure for residents and tourists alike centers around water recreation. I urge DEP to lead the nation on protecting public health by setting protective recreational exposure standards to prevent mounting human health issues alongside an ecological crisis.

The intensity and expanse of blue-green algae we experienced in the summer of 2018 proved to us that ingestion is not the only mode of exposure. The EPA's final recommendations do not account for the additional modes of exposure by air, dermal contact and consumption of contaminated seafood - so lower, more protective levels should be set by the state while research continues to study the health effects. I urge you not to wait to protect the public.

Dear Environmental Consultant Kaitlyn Sutton,

My husband and I both make our living on the water and our children spend the majority of their time playing and exploring our waters. I urge DEP to lead the nation on protecting public health by setting protective recreational exposure standards to prevent mounting human health issues alongside an ecological crisis.

The intensity and expanse of blue-green algae we experienced in the summer of 2018 proved to us that ingestion is not the only mode of exposure. The EPA's final recommendations do not account for the additional modes of exposure by air, dermal contact and consumption of contaminated seafood - so lower, more protective levels should be set by the state while research continues to study the health effects. I urge you not to wait to protect the public. We'll never regret being proactive on this issue. Thank you for your time and service to our community.

Florida's allure for residents and tourists alike centers around water recreation. I urge DEP to lead the nation on protecting public health by setting protective recreational exposure standards to prevent mounting human health issues alongside an ecological crisis.

The intensity and expanse of blue-green algae we experienced in the summer of 2018 proved to us that ingestion is not the only mode of exposure. The EPA's final recommendations do not account for the additional modes of exposure by air, dermal contact and consumption of contaminated seafood - so lower, more protective levels should be set by the state while research continues to study the health effects. I urge you not to wait to protect the public.

Regards,

**Date:** Tuesday, November 19, 2019 3:22:34 AM

---

Dear Florida Department of Environmental Protection,

For the last 32 years I have been flying from Illinois to Florida at least twice every year to fish for bass on the St John's River. Until this year the experience has been a wonderful one, allowing me to enjoy the real pleasures of the great out-of-doors along a terrific waterway and producing tremendous catch-and-release bass fishing out of Welaka and Georgetown. This year the three guides I utilized decided against fishing on the St John's because of the algae bloom which was covering the river and Lake George. Also, there was no eelgrass on the river and, thus, no shiners and no successful bass fishing. I am having second thoughts about whether Florida is the place to fish since I have also had very successful fishing trips to Ontario and to Labrador in Canada and elsewhere in the northern US. I have also been reading about how politically-connected businesses are being allowed to pollute the St John's and how, increasingly, more and more waterways are inundated with out-of-control algae blooms caused by industrial pollution. Why should I spend a lot of money visiting Florida if the State of Florida is not interested enough in its fisheries to protect them?

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. I'm counting on you to take action to assure that Florida does not become a fishing wasteland.

Dear Florida Department of Environmental Protection,

Please establish new, clear standards for cyanotoxins in water. Algae blooms are a serious problem in Florida. The toxins they produce threaten human health and wildlife.

By establishing criteria for cyanotoxins, you can set clear numeric baselines for our state's recreational waters. This will create a basis for monitoring and help officials know when blooms become dangerous.

Relying only on the visual presence of an algae bloom is inadequate and doesn't allow for persistent toxins. Research shows that toxins can persist after algae is no longer visible, concentrations can actually be higher, and that for some toxins, the highest concentrations are below the water surface.

I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria, and far better than the final version issued by the EPA earlier this year.

Please take advantage of this opportunity for Florida to be a leader in adoption of water-quality criteria for cyanotoxins.

Help save our beautiful state.

Dear Environmental Consultant Kaitlyn Sutton,

In 2019, Governor DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governor appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period. Please adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Dear Environmental Consultant Kaitlyn Sutton,

In 2019, Governor DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governor appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period. Please adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Regards,  
Vladimir Trainin

Dear Environmental Consultant Kaitlyn Sutton,

Water quality is of critical importance to the citizens of Florida. The 2016 standards set by the EPA (4 micrograms per liter for microcystins and 8 micrograms per liter for cylindrospermopsin) clearly provide more protection for citizens than the more recent EPA recommendation, which was based on a limited definition of ingestion methods - not an adequate means of protecting our citizens given the reality of other injection methods. As a native Floridian and an active voter, I encourage the DEP to set the standards in line with the more thorough 2016 EPA recommendations. Thank you.

Dear Environmental Consultant Kaitlyn Sutton,

In 2019, Governor DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governor appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period. Dear Environmental Consultant Kaitlyn Sutton,

In 2019, Governor DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governor appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period. Please adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Regards,  
Jerry Edelman  
1119 Periwinkle Way  
Sanibel, FL 33957

Dear Environmental Consultant Kaitlyn Sutton,

I am writing to strongly urge you to backup Governor DeSantis' Florida Blue-Green Algae Task Force "to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state's natural resources and enforce its environmental laws." The scientists the Governor appointed to the task force have urged our state to take immediate and strong action - and importantly not to await additional research before establishing water quality criteria for cyanotoxins.

Clearly, Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without establishing and enforcing targets, nothing will change and the public will continue to be harmed. I urge you to please set protective standards in this rule-making period.

Please adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

---

Dear Environmental Consultant Kaitlyn Sutton,

In 2019, Governor DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governor appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period. Please adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Regards,  
Alex Roveda

Rogue River, OR 97537

Dear Environmental Consultant Kaitlyn Sutton,

In 2019, Governor DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governor appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period. Please adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin. We are annual winter FLORIDA residents and have children and grandchildren who are permanent residents, so this issue very important to us.

Dear Environmental Consultant Kaitlyn Sutton,

I am writing to ask the DEP to establish cyanotoxin standards to protect public health in recreational waters.

Research on cyanotoxin blooms has indicated that exposure to blooms has serious ill effects on humans, pets and livestock from the ingestion of water, skin contact and inhalation.

Please don't gamble with our health. We need DEP to establish strong, protective numeric limits this year. We can't afford to wait.

---

Dear Environmental Consultant Kaitlyn Sutton,

In 2019, Governor DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governor appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period. Please adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Regards,  
Kimberly Glick

Cape Coral, FL 33904

---

Dear Environmental Consultant Kaitlyn Sutton,

In 2019, Governor DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governor appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period. Please adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Regards,  
Valerie Franklin  
11511 Wellfleet Dr  
Fort Myers, FL 33908

Dear Environmental Consultant Kaitlyn Sutton,

In 2019, Governor DeSantis established the Florida Blue-Green Algae Task Force “to aid the Department of Environmental Protection in fulfilling its mission to protect, conserve and manage the state’s natural resources and enforce its environmental laws.” The scientists the Governor appointed to the task force have urged the state to take immediate action and not to wait on additional research before establishing water quality criteria for cyanotoxins. In their amended Draft Consensus Document, they include “stronger” language to reflect the consensus of its members.

Florida needs a protective toxin standard by which to measure public safety in the water. Like speed limit signs, a protective numeric exposure level is needed to trigger warnings and measure the trends in recreational waters. Without such targets, nothing will change and the public will be harmed. I urge you to please set protective standards in this rule-making period. Please adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Regards,  
John mccabe  
2688 Coconut Dr  
Sanibel, FL 33957

**Subject:** Stop the pollution. Please Establish Water-quality Criteria  
**Date:** Monday, November 18, 2019 7:19:39 AM

---

Dear Florida Department of Environmental Protection,

Please don't pass the buck down to our children by drilling discard Wells.

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Jason Helvenston

Dear Environmental Specialist Kaitlyn Sutton,

I request that the Florida Department of Environmental Protection (FDEP) set water quality standards for the cyanotoxins microcystin and cylindrospermopsin as part of the triennial review process. These toxins result from outbreaks of blue green algae that are on the increase in Florida, placing people, pets, and wildlife at risk of dangerous levels of exposure.

The FDEP should follow the protective health exposure standards of 4 micrograms per liter for microcystins and 8 micrograms per liter for cylindrospermopsin that were recommended as part of US EPA draft standards released in 2016. While EPA later issued a final recommendation allowing for higher limits, these are not adequately protective of human health considering the many ways in which Florida's residents and visitors can be exposed beyond direct ingestion. Those exposures include through inhalation, dermal exposure and the consumption of contaminated fish or shellfish—all of which are common in Florida due to year-round recreational use of waterways and high levels of seafood consumption as a coastal state.

Gov. Ron DeSantis recognized the seriousness of these issues in establishing the Florida Blue-Green Algae Task Force to help guide state actions in addressing increasing outbreaks of blue green algae. The Task Force recently recommended that health advisories and water quality criteria for cyanotoxins be developed by the state.

Considering the overwhelming evidence of harm to humans, domesticated animals, and waterways from exposure to cyanotoxins, I request that you act immediately to create protective standards.

Sincerely,  
Ms. Kathleen Williams

Dear Environmental Consultant Kaitlyn Sutton,

Southwest Florida has experienced several harmful algal blooms with the 2018 event lasting nearly a year. People, their pets and livestock got sick and some died from cyanotoxins. No public warnings or public education were provided to protect the public from the exposure that occurs from skin contact, inhalation or ingestion. Serious illnesses including liver and neurodegenerative diseases are associated with cyanotoxins yet Florida has no standards. Our water is our economy -- when our water is toxic so goes our economic health, no one comes to play in toxic water.

Take responsible action. I urge you to adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Dear Environmental Consultant Kaitlyn Sutton,

Southwest Florida has experienced several harmful algal blooms with the 2018 event lasting nearly a year. People, their pets and livestock got sick and some died from cyanotoxins. No public warnings or public education were provided to protect the public from the exposure that occurs from skin contact, inhalation or ingestion. Serious illnesses including liver and neurodegenerative diseases are associated with cyanotoxins yet Florida has no standards. Our water is our economy -- when our water is toxic so goes our economic health, no one comes to play in toxic water.

Take responsible action. I urge you to adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Regards,  
Robert Feik

Dear Environmental Consultant Kaitlyn Sutton,

I am deeply concerned about the dangers presented by toxic cyanobacteria, or blue-green algae. Our water is our economy -- when our water is toxic so goes our economic health, no one comes to play in toxic water.

Take responsible action. I urge you to adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Dear Environmental Consultant Kaitlyn Sutton,

It is imperative that Florida establish protective health exposure standards of 4 micrograms per liter for Microsystems and 8 micrograms per liter for cylindrospermopsin.

As a Florida property owner and soon to be resident, I have witnessed the devastation caused by these water and air toxins.

Please keep Florida's citizens, wildlife, domestic pets and visitors safe!

Dear Environmental Consultant Kaitlyn Sutton,

Southwest Florida has experienced several harmful algal blooms with the 2018 event lasting nearly a year. People, their pets and livestock got sick and some died from cyanotoxins. No public warnings or public education were provided to protect the public from the exposure that occurs from skin contact, inhalation or ingestion. Serious illnesses including liver and neurodegenerative diseases are associated with cyanotoxins yet Florida has no standards. Our water is our economy -- when our water is toxic so goes our economic health, no one comes to play in toxic water.

Take responsible action. I urge you to adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Dear Environmental Consultant Kaitlyn Sutton,

What would you do if it were you child or loved one that was in Toxic water without warning.  
I live year round on Sanibel Island where that is exactly what's happening !!!1

DO SOMETHING !!!

adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Dear Environmental Consultant Kaitlyn Sutton,

Southwest Florida has experienced several harmful algal blooms with the 2018 event lasting nearly a year. People, their pets and livestock got sick and some died from cyanotoxins. No public warnings or public education were provided to protect the public from the exposure that occurs from skin contact, inhalation or ingestion. Serious illnesses including liver and neurodegenerative diseases are associated with cyanotoxins yet Florida has no standards. Our water is our economy -- when our water is toxic so goes our economic health, no one comes to play in toxic water.

Take responsible action. I urge you to adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Dear Environmental Consultant Kaitlyn Sutton,

Last year my parents both had pneumonia in SW Florida and nearly died. Normally I'd say it's coincidence except my father has never been to the hospital. He and my mother are Florida residents and were here when the algae content was toxic - killing every fish in San Carlos bay. Please address the pollutants which amplify these toxic algae blooms.

Southwest Florida has experienced several harmful algal blooms with the 2018 event lasting nearly a year. People, their pets and livestock got sick and some died from cyanotoxins. Dear Environmental Consultant Kaitlyn Sutton,

Southwest Florida has experienced several harmful algal blooms with the 2018 event lasting nearly a year. People, their pets and livestock got sick and some died from cyanotoxins. No public warnings or public education were provided to protect the public from the exposure that occurs from skin contact, inhalation or ingestion. Serious illnesses including liver and neurodegenerative diseases are associated with cyanotoxins yet Florida has no standards. Our water is our economy -- when our water is toxic so goes our economic health, no one comes to play in toxic water.

Take responsible action. I urge you to adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Regards,  
Kathleen LaMotte  
5657 Baltusrol Ct  
Sanibel, FL 33957

Dear Environmental Consultant Kaitlyn Sutton,

Southwest Florida has experienced several harmful algal blooms with the 2018 event lasting nearly a year. People, their pets and livestock got sick and some died from cyanotoxins. No public warnings or public education were provided to protect the public from the exposure that occurs from skin contact, inhalation or ingestion. Serious illnesses including liver and neurodegenerative diseases are associated with cyanotoxins yet Florida has no standards. Our water is our economy -- when our water is toxic so goes our economic health, no one comes to play in toxic water.

Take responsible action. I urge you to adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Regards,  
Robert Diefenbach  
1910 Virginia Ave  
Fort Myers, FL 33901

Dear Environmental Consultant Kaitlyn Sutton,

We have owned a condo in Sanibel, Florida since 1985 and have been horrified with the lack of environmental protection we have received from the state. We have seen the water quality continue to kill the fish and other sea life. The many birds that used to feed in this area have declined due to them being killed by eating infected fish or finding other places to go. Why???? I am affected by the air quality as well and cannot enjoy my beach walks as I used to because of my coughing. The frequency of the red tide has become pronounced. We are doing all we can at Sanibel in being good stewards, but the rest of the state is continuing to pollute with their use of fertilizers. We now have cane toads that are infecting our swimming pool. WHY???? Would you want your grandchildren to be exposed to this toxic species? Please use your position to take action immediately. This has gone on far too long.

No public warnings or public education were provided to protect the public from the exposure that occurs from skin contact, inhalation or ingestion. Serious illnesses including liver and neurodegenerative diseases are associated with cyanotoxins yet Florida has no standards. Our water is our economy -- when our water is toxic so goes our economic health, no one comes to play in toxic water.

Take responsible action. I urge you to adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Regards,  
Raymond Bissonnette  
143 Dahlia St

Dear Environmental Consultant Kaitlyn Sutton,

Southwest Florida has experienced several harmful algal blooms with the 2018 event lasting nearly a year. People, their pets and livestock got sick and some died from cyanotoxins. No public warnings or public education were provided to protect the public from the exposure that occurs from skin contact, inhalation or ingestion. Serious illnesses including liver and neurodegenerative diseases are associated with cyanotoxins yet Florida has no standards. Our water is our economy -- when our water is toxic so goes our economic health, no one comes to play in toxic water.

Take responsible action. I urge you to adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin.

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Betty Nimcheski

Dear Ms. Sutton,

I strongly support the establishing standards for water quality limits for toxic algae.

As you know, this summer an algae bloom in Melbourne's Lake apparently went undetected, unmeasured and untreated until complaints from local residents about taste, odor, and health concerns.

Water used for irrigation must to be monitored as well because the toxins from cyanobacteria have been found to survive treatment and are present in foods irrigated with such water.

Without limits and consistent measurement, we cannot be sure that toxic algae will be detected and treated effectively to avoid significant impacts to public health.

It is imperative Florida implement clear water quality limits for toxic algae.

Thank you,  
Marilyn Meyer

My husband and I have been visiting Florida for 25 years and hope to make this our new home soon. Last year, when we walked the beaches, there was a definite issue with breathing. We would find ourselves coughing and sneezing — just so much worse than anything we have ever experienced.

Let's get this draft adopted for everyone who lives here or loves to visit.

Thank you.

Dear Official, Please adopt the 2016 EPA draft recommended water quality criteria of 4 micrograms per liter for microcystin and 8 micrograms per liter for cylindrospermopsin to best protect recreational users and restore Florida's imperiled waters.

We need to address these matters now. This is not only about health but also the economic engine that drives the Florida Economy.

What are we waiting for??  
Rob Corso

Dear Official,

Please adopt the 2016 EPA draft recommended water quality criteria of 4 micrograms per liter for microcystin and 8 micrograms per liter for cylindrospermopsin to best protect recreational users and restore Florida's imperiled waters.

As life-long Floridians, we value our waterways, resident health, sea life, tourist dollars, pristine views . . .

Thank you!

Dear Official,

Please adopt the 2016 EPA draft recommended water quality criteria of 4 micrograms per liter for microcystin and 8 micrograms per liter for cylindrospermopsin to best protect recreational users and restore Florida's imperiled waters.

We live on Fort Myers Beach and have been adversely impacted by the stench of the water and dead fish on our beach!

This is VERY important to us!

Sincerely,  
Marilyn

Dear Official, Please adopt the 2016 EPA draft recommended water quality criteria of 4 micrograms per liter for microcystin and 8 micrograms per liter for cylindrospermopsin to best protect recreational users and restore Florida's imperiled waters.

We know that drinking, touching, and even breathing algae-borne toxins can cause skin rashes, eye irritation, nose and throat irritation and breathing difficulty, stomach and intestinal problems, and liver damage. Additionally researchers have linked these toxins to increased risks of liver failure, ALS, Alzheimer's Disease, Parkinson's Disease, and multiple cancers.

Dear Official, Please adopt the 2016 EPA draft recommended water quality criteria of 4 micrograms per liter for microcystin and 8 micrograms per liter for cylindrospermopsin to best protect recreational users and restore Florida's imperiled waters.

While I have written to you before, I have never felt before that Florida's need for environmental protection has ever been so great. When I was an activist in the Tampa Bay Water Wars, I felt that I was a Republican voice of reason when I asked for protections on water quality, as well as water quantities withdrawn from the Floridan Aquifer. Environmental protections are far less expensive than environmental restorations. Take a look at the Florida Everglades, we have not only reduced the flow of water to the River of Grass, but we have degraded the water quality to dangerous levels of nitrates and toxins into every area that is touched by this flow.

Now is the time to be strong and improve water quality regulations. If we wait much longer, we may cause irreparable harm to the fragile ecosystems in the state and cause a mass exodus from the State of Florida by residents and tourists.

Please keep this in mind.

Sincerely,

Judy A. Williams

Dear Official, Please adopt the most protective water quality criteria for cyanotoxins that would protect recreational users and restore Florida's imperiled waters.

My home on Little Gasparilla Island has become uninhabital because of red tide.. My husband and I developed coughs from breathing the air, which developed into respiratory problems.

My grandchildren no longer want to visit because of dead fish littering the beach and the odor. Please, we need this problem resolved.

Thank you,  
Sarah Cook

Dear Official,

Please adopt the 2016 EPA draft recommended water quality criteria of 4 micrograms per liter for microcystin and 8 micrograms per liter for cylindrospermopsin to best protect recreational users and restore Florida's imperiled waters.

My wife and I just recently completed building and moved into our new home on the banks of the St. Lucie River. During construction last year, we witnessed the green sludge as it churned around our dock. Even walking out on the dock it was difficult to breathe. I still wonder if I did some amount of permanent damage to my health being so close to the cyanobacteria blooms.

Our house is set a bit back from the water, but just because I can't see or smell the algae, does that mean I'm safe? I'm not sure anyone knows. Please help reduce the threat to our children, our pets and our lives by establishing safe limits for these dangerous environmental toxins.

Billy

As a SWFL full time fishing guide, this issue is not only hits "close to home", it's my front yard as well as hundreds of other guides that rely on a healthy fishery. We would all appreciate it if standards were raised not only to protect our "front yard" and our public health but to set an example for how things should continue in the future for the Okeechobee and Everglades watershed as well as all other economically and recreationally important systems in FL. Thank you.

Dear Official, Please adopt the 2016 EPA draft recommended water quality criteria of 4 micrograms per liter for microcystin and 8 micrograms per liter for cylindrospermopsin to best protect recreational users and restore Florida's imperiled waters.

I'm an owner of two beach properties on Fort Myers Beach. We thoroughly enjoy the beach and love spending time there. So you our kids and grand kids. We are however afraid of the water and the air around FMB because of the discharges. Our allergies are proof to us that something is going on as they flare up when we are on the island. Please consider the people who spend time on the beach.

Tom VanderBie

Dear Florida water quality professional,

Please adopt the 2016 EPA draft recommended water quality criteria of 4 micrograms per liter for microcystin and 8 micrograms per liter for cylindrospermopsin to best protect recreational users and restore Florida's imperiled waters.

Please act as if you actually live her and have to struggle through this!! It is crushing the one basket we have for revenue....tourism...and our ongoing viability as a state.

What is happening to Florida is a shame when it can all be helped if not for the greed!!! I'm sick of seeing my beautiful beaches of Sanibel And Captiva islands... and Naples being littered with fish suffocated by this algae!!  
FOR THE LOVE OF GOD DO SOMETHING!!!!!!!!!!!!

Dear Official, Please adopt the 2016 EPA draft recommended water quality criteria of 4 micrograms per liter for microcystin and 8 micrograms per liter for cylindrospermopsin to best protect recreational users and restore Florida's imperiled waters.

As a Stuart resident residing along the St Lucie River for 35 years, I am greatly concerned about the long term impacts of blue green algae blooms that continue to put the health of my family in jeopardy year after year. Please do what you must to protect the public from toxic algae outbreaks.

Sincerely, David Preston

**Subject:** Urgent! Please Establish Water-quality Criteria for Cyanotoxins  
**Date:** Saturday, November 23, 2019 4:11:27 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
James Sorrells  
Clermont, FL 34715

**Subject:** Water quality criteria for cyanotoxins  
**Date:** Tuesday, November 19, 2019 4:46:01 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know, harmful algae blooms are a serious problem, and the cyanotoxins they produce threaten human health and that of our native wildlife. Exposures to these dangerous toxins can occur through polluted water, contaminated seafood, skin exposure, or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric standards for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. Such criteria also would help the department address the array of factors that lead to these blooms from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums; the highest concentrations are below the surface of the water.

For all these reasons, I urge your department to adopt new criteria using the U.S. Environmental Protection Agency's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far better than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to put in place strong water quality criteria for cyanotoxins. We're counting on you to protect Florida's residents, visitors, and native wildlife.

Sincerely,  
Elizabeth Wright  
Apalachicola, FL 32320

**Subject:** Water Quality Limits for Toxic Algae  
**Date:** Thursday, November 21, 2019 9:49:12 PM

---

Dear Ms. Sutton,

According to a recent story published by WLRN.org, your agency is currently accepting public comments regarding water quality limits for toxic algae. I am writing to strongly support the establishment of such standards.

This summer, a local drinking water source, Lake Washington in Melbourne, experienced an algae bloom that apparently went undetected, unmeasured, and untreated until complaints from local residents about taste, odor, and health concerns.

Water used for irrigation must be monitored as well because the toxins from cyanobacteria have been found to survive treatment and are present in foods irrigated with such water.

Without limits and consistent measurement, we cannot be sure that toxic algae will be detected and treated effectively to avoid significant impacts to public health.

Please implement clear water quality limits for toxic algae in Florida.

Sincerely,

***Claudia M. Thomas***

**Subject:** Water Quality Standards need to be strengthened in the triennial review process  
**Date:** Tuesday, November 19, 2019 12:33:06 PM

---

Dear Environmental Specialist Kaitlyn Sutton,

I request that the Florida Department of Environmental Protection (FDEP) set water quality standards for the cyanotoxins microcystin and cylindrospermopsin as part of the triennial review process. These toxins result from outbreaks of blue green algae that are on the increase in Florida, placing people, pets, and wildlife at risk of dangerous levels of exposure.

The FDEP should follow the protective health exposure standards of 4 micrograms per liter for microcystins and 8 micrograms per liter for cylindrospermopsin that were recommended as part of US EPA draft standards released in 2016. While EPA later issued a final recommendation allowing for higher limits, these are not adequately protective of human health considering the many ways in which Florida's residents and visitors can be exposed beyond direct ingestion. Those exposures include through inhalation, dermal exposure and the consumption of contaminated fish or shellfish—all of which are common in Florida due to year-round recreational use of waterways and high levels of seafood consumption as a coastal state.

Gov. Ron DeSantis recognized the seriousness of these issues in establishing the Florida Blue-Green Algae Task Force to help guide state actions in addressing increasing outbreaks of blue green algae. The Task Force recently recommended that health advisories and water quality criteria for cyanotoxins be developed by the state.

Considering the overwhelming evidence of harm to humans, domesticated animals, and waterways from exposure to cyanotoxins, I request that you act immediately to create protective standards.

Thank you,

Sincerely,

**Date:** Tuesday, November 19, 2019 3:09:31 PM

---

Dear Environmental Specialist Kaitlyn Sutton,

I request that the Florida Department of Environmental Protection (FDEP) set water quality standards for the cyanotoxins microcystin and cylindrospermopsin as part of the triennial review process. These toxins result from outbreaks of blue green algae that are on the increase in Florida, placing people, pets, and wildlife at risk of dangerous levels of exposure.

The FDEP should follow the protective health exposure standards of 4 micrograms per liter for microcystins and 8 micrograms per liter for cylindrospermopsin that were recommended as part of US EPA draft standards released in 2016. While EPA later issued a final recommendation allowing for higher limits, these are not adequately protective of human health considering the many ways in which Florida's residents and visitors can be exposed beyond direct ingestion. Those exposures include through inhalation, dermal exposure and the consumption of contaminated fish or shellfish—all of which are common in Florida due to year-round recreational use of waterways and high levels of seafood consumption as a coastal state.

Gov. Ron DeSantis recognized the seriousness of these issues in establishing the Florida Blue-Green Algae Task Force to help guide state actions in addressing increasing outbreaks of blue green algae. The Task Force recently recommended that health advisories and water quality criteria for cyanotoxins be developed by the state.

Considering the overwhelming evidence of harm to humans, domesticated animals, and waterways from exposure to cyanotoxins, I request that you act immediately to create protective standards.

**Date:** Tuesday, November 19, 2019 3:25:25 PM

---

Dear Environmental Specialist Kaitlyn Sutton,

I request that the Florida Department of Environmental Protection (FDEP) set water quality standards for the cyanotoxins microcystin and cylindrospermopsin as part of the triennial review process. These toxins result from outbreaks of blue green algae that are on the increase in Florida, placing people, pets, and wildlife at risk of dangerous levels of exposure.

The FDEP should follow the protective health exposure standards of 4 micrograms per liter for microcystins and 8 micrograms per liter for cylindrospermopsin that were recommended as part of US EPA draft standards released in 2016. While EPA later issued a final recommendation allowing for higher limits, these are not adequately protective of human health considering the many ways in which Florida's residents and visitors can be exposed beyond direct ingestion. Those exposures include through inhalation, dermal exposure and the consumption of contaminated fish or shellfish—all of which are common in Florida due to year-round recreational use of waterways and high levels of seafood consumption as a coastal state.

Gov. Ron DeSantis recognized the seriousness of these issues in establishing the Florida Blue-Green Algae Task Force to help guide state actions in addressing increasing outbreaks of blue green algae. The Task Force recently recommended that health advisories and water quality criteria for cyanotoxins be developed by the state.

Considering the overwhelming evidence of harm to humans, domesticated animals, and waterways from exposure to cyanotoxins, I request that you act immediately to create protective standards.

Thank you,

Sincerely,  
Mr Robert Oberdorf

I request that the Florida Department of Environmental Protection (FDEP) set water quality standards for the cyanotoxins microcystin and cylindrospermopsin as part of the triennial review process. These toxins result from outbreaks of blue green algae that are on the increase in Florida, placing people, pets, and wildlife at risk of dangerous levels of exposure.

The FDEP should follow the protective health exposure standards of 4 micrograms per liter for microcystins and 8 micrograms per liter for cylindrospermopsin that were recommended as part of US EPA draft standards released in 2016. While EPA later issued a final recommendation allowing for higher limits, these are not adequately protective of human health considering the many ways in which Florida's residents and visitors can be exposed beyond direct ingestion. Those exposures include through inhalation, dermal exposure and the consumption of contaminated fish or shellfish—all of which are common in Florida due to year-round recreational use of waterways and high levels of seafood consumption as a coastal state.

Gov. Ron DeSantis recognized the seriousness of these issues in establishing the Florida Blue-Green Algae Task Force to help guide state actions in addressing increasing outbreaks of blue green algae. The Task Force recently recommended that health advisories and water quality criteria for cyanotoxins be developed by the state.

Considering the overwhelming evidence of harm to humans, domesticated animals, and waterways from exposure to cyanotoxins, I request that you act immediately to create protective standards.

Thank you,

Sincerely,  
Ms Sissi Asperti  
1150 Euclid Ave Apt 308 Miami Beach, FL 33139-4568

Dear Environmental Specialist Kaitlyn Sutton,

I strongly but respectfully request that the Florida Department of Environmental Protection (FDEP) set water quality standards for the cyanotoxins microcystin and cylindrospermopsin as part of the triennial review process. These toxins result from outbreaks of blue green algae that are on the increase in Florida, placing people, pets, and wildlife at risk of dangerous levels of exposure.

The FDEP should follow the protective health exposure standards of 4 micrograms per liter for microcystins and 8 micrograms per liter for cylindrospermopsin that were recommended as part of US EPA draft standards released in 2016. While EPA later issued a final recommendation allowing for higher limits, these are not adequately protective of human health considering the many ways in which Florida's residents and visitors can be exposed beyond direct ingestion. Those exposures include through inhalation, dermal exposure and the consumption of contaminated fish or shellfish—all of which are common in Florida due to year-round recreational use of waterways and high levels of seafood consumption as a coastal state.

Gov. Ron DeSantis recognized the seriousness of these issues in establishing the Florida Blue-Green Algae Task Force to help guide state actions in addressing increasing outbreaks of blue green algae. The Task Force recently recommended that health advisories and water quality criteria for cyanotoxins be developed by the state.

Considering the overwhelming evidence of harm to humans, domesticated animals, and waterways from exposure to cyanotoxins, I request that you act immediately to create protective standards.

Thank you,

Sincerely,  
Mrs. Joan Walker

Those exposures include through inhalation, dermal exposure and the consumption of contaminated fish or shellfish—all of which are common in Florida due to year-round recreational use of waterways and high levels of seafood consumption as a coastal state.

Gov. Ron DeSantis recognized the seriousness of these issues in establishing the Florida Blue-Green Algae Task Force to help guide state actions in addressing increasing outbreaks of blue green algae. The Task Force recently recommended that health advisories and water quality criteria for cyanotoxins be developed by the state.

Considering the overwhelming evidence of harm to humans, domesticated animals, and waterways from exposure to cyanotoxins, I request that you act immediately to create protective standards.

Thank you,

Sincerely,  
Mrs Judith Peter

---

Dear Environmental Specialist Kaitlyn Sutton,

I request that the Florida Department of Environmental Protection (FDEP) set water quality standards for the cyanotoxins microcystin and cylindrospermopsin as part of the triennial review process. These toxins result from outbreaks of blue green algae that are on the increase in Florida, placing people, pets, and wildlife at risk of dangerous levels of exposure.

The FDEP should follow the protective health exposure standards of 4 micrograms per liter for microcystins and 8 micrograms per liter for cylindrospermopsin that were recommended as part of US EPA draft standards released in 2016. While EPA later issued a final recommendation allowing for higher limits, these are not adequately protective of human health considering the many ways in which Florida's residents and visitors can be exposed beyond direct ingestion. Those exposures include through inhalation, dermal exposure and the consumption of contaminated fish or shellfish—all of which are common in Florida due to year-round recreational use of waterways and high levels of seafood consumption as a coastal state.

Gov. Ron DeSantis recognized the seriousness of these issues in establishing the Florida Blue-Green Algae Task Force to help guide state actions in addressing increasing outbreaks of blue green algae. The Task Force recently recommended that health advisories and water quality criteria for cyanotoxins be developed by the state.

Considering the overwhelming evidence of harm to humans, domesticated animals, and waterways from exposure to cyanotoxins, I request that you act immediately to create protective standards.

The Task Force recently recommended that health advisories and water quality criteria for cyanotoxins be developed by the state. Having meetings and making recommendations are all good but action is what is needed. And action that will get results.

Outdoor activities are a major part of Florida's economy. People come here to enjoy our beautiful beaches and preserves. That is not much fun when the waterways are toxic. This should be obvious to all. Considering the overwhelming evidence of harm to humans, domesticated animals, and waterways from exposure to cyanotoxins, I request that you act immediately to create protective standards.

**Subject:** Water Quality Standards need to be strengthened in the triennial review process  
**Date:** Tuesday, November 19, 2019 6:44:00 PM

---

Dear Environmental Specialist Kaitlyn Sutton,

I request that the Florida Department of Environmental Protection (FDEP) set water quality standards for the cyanotoxins microcystin and cylindrospermopsin as part of the triennial review process. These toxins result from outbreaks of blue green algae that are on the increase in Florida, placing people, pets, and wildlife at risk of dangerous levels of exposure.

The FDEP should follow the protective health exposure standards of 4 micrograms per liter for microcystins and 8 micrograms per liter for cylindrospermopsin that were recommended as part of US EPA draft standards released in 2016. While EPA later issued a final recommendation allowing for higher limits, these are not adequately protective of human health considering the many ways in which Florida's residents and visitors can be exposed beyond direct ingestion. Those exposures include through inhalation, dermal exposure and the consumption of contaminated fish or shellfish—all of which are common in Florida due to year-round recreational use of waterways and high levels of seafood consumption as a coastal state.

Gov. Ron DeSantis recognized the seriousness of these issues in establishing the Florida Blue-Green Algae Task Force to help guide state actions in addressing increasing outbreaks of blue green algae. The Task Force recently recommended that health advisories and water quality criteria for cyanotoxins be developed by the state.

Considering the overwhelming evidence of harm to humans, domesticated animals, and waterways from exposure to cyanotoxins, I request that you act immediately to create protective standards.

Thank you,

Sincerely,  
Ms. Alicia Addeo

---

Dear Environmental Specialist Kaitlyn Sutton,

I request that the Florida Department of Environmental Protection (FDEP) set water quality standards for the cyanotoxins microcystin and cylindrospermopsin as part of the triennial review process. These toxins result from outbreaks of blue green algae that are on the increase in Florida, placing people, pets, and wildlife at risk of dangerous levels of exposure.

The FDEP should follow the protective health exposure standards of 4 micrograms per liter for microcystins and 8 micrograms per liter for cylindrospermopsin that were recommended as part of US EPA draft standards released in 2016. While EPA later issued a final recommendation allowing for higher limits, these are not adequately protective of human health considering the many ways in which Florida's residents and visitors can be exposed beyond direct ingestion. Those exposures include through inhalation, dermal exposure and the consumption of contaminated fish or shellfish—all of which are common in Florida due to year-round recreational use of waterways and high levels of seafood consumption as a coastal state.

Gov. Ron DeSantis recognized the seriousness of these issues in establishing the Florida Blue-Green Algae Task Force to help guide state actions in addressing increasing outbreaks of blue green algae. The Task Force recently recommended that health advisories and water quality criteria for cyanotoxins be developed by the state.

Considering the overwhelming evidence of harm to humans, domesticated animals, and waterways from exposure to cyanotoxins, I request that you act immediately to create protective standards.

Thank you,

Sincerely,  
Ms. Eileen Riccio

The FDEP should follow the protective health exposure standards of 4 micrograms per liter for microcystins and 8 micrograms per liter for cylindrospermopsin that were recommended as part of US EPA draft standards released in 2016. While EPA later issued a final recommendation allowing for higher limits, these are not adequately protective of human health considering the many ways in which Florida's residents and visitors can be exposed beyond direct ingestion. Those exposures include through inhalation, dermal exposure and the consumption of contaminated fish or shellfish—all of which are common in Florida due to year-round recreational use of waterways and high levels of seafood consumption as a coastal state.

Gov. Ron DeSantis recognized the seriousness of these issues in establishing the Florida Blue-Green Algae Task Force to help guide state actions in addressing increasing outbreaks of blue green algae. The Task Force recently recommended that health advisories and water quality criteria for cyanotoxins be developed by the state.

Considering the overwhelming evidence of harm to humans, domesticated animals, and waterways from exposure to cyanotoxins, I request that you act immediately to create protective standards.

Thank you,

Sincerely,  
Mr. Richard Bourne

Dear Environmental Specialist Kaitlyn Sutton,

I request that the Florida Department of Environmental Protection (FDEP) set water quality standards for the cyanotoxins microcystin and cylindrospermopsin as part of the triennial review process. These toxins result from outbreaks of blue green algae that are on the increase in Florida, placing people, pets, and wildlife at risk of dangerous levels of exposure.

The FDEP should follow the protective health exposure standards of 4 micrograms per liter for microcystins and 8 micrograms per liter for cylindrospermopsin that were recommended as part of US EPA draft standards released in 2016. While EPA later issued a final recommendation allowing for higher limits, these are not adequately protective of human health considering the many ways in which Florida's residents and visitors can be exposed beyond direct ingestion. Those exposures include through inhalation, dermal exposure and the consumption of contaminated fish or shellfish—all of which are common in Florida due to year-round recreational use of waterways and high levels of seafood consumption as a coastal state.

**Date:** Wednesday, November 20, 2019 6:42:12 PM

---

Dear Environmental Specialist Kaitlyn Sutton,

I request that the Florida Department of Environmental Protection (FDEP) set water quality standards for the cyanotoxins microcystin and cylindrospermopsin as part of the triennial review process. These toxins result from outbreaks of blue green algae that are on the increase in Florida, placing people, pets, and wildlife at risk of dangerous levels of exposure.

The FDEP should follow the protective health exposure standards of 4 micrograms per liter for microcystins and 8 micrograms per liter for cylindrospermopsin that were recommended as part of US EPA draft standards released in 2016. While EPA later issued a final recommendation allowing for higher limits, these are not adequately protective of human health considering the many ways in which Florida's residents and visitors can be exposed beyond direct ingestion. Those exposures include through inhalation, dermal exposure and the consumption of contaminated fish or shellfish—all of which are common in Florida due to year-round recreational use of waterways and high levels of seafood consumption as a coastal state.

Gov. Ron DeSantis recognized the seriousness of these issues in establishing the Florida Blue-Green Algae Task Force to help guide state actions in addressing increasing outbreaks of blue green algae. The Task Force recently recommended that health advisories and water quality criteria for cyanotoxins be developed by the state.

Considering the overwhelming evidence of harm to humans, domesticated animals, and waterways from exposure to cyanotoxins, I request that you act immediately to create protective standards.

**Subject:** Water-quality Criteria for Cyanotoxins  
**Date:** Monday, November 18, 2019 11:44:29 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Theresa Lianzi

Dear Florida Department of Environmental Protection,

We don't need to lose any more tourist jobs, that's why I am writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

**Subject:** We Must Establish Water-quality Criteria for Cyanotoxins  
**Date:** Monday, November 18, 2019 10:35:35 PM

---

Dear Florida Department of Environmental Protection,

Please establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. We all are aware harmful algae blooms are a growing problem. The cyanotoxins they produce are threatening human health and wildlife. I am very sensitive to its effects, living 5 minutes from the water. People are exposed many ways to them through polluted water, contaminated seafood, skin exposure or inhalation. It makes me cough, irritates my throat and makes it hard for me to breathe.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.
