**Subject:** "Concern with Triennial Review of Water Quality Standards"  
**Date:** Wednesday, November 20, 2019 10:39:16 PM

---

To whom it may concern,

I am speaking up in concern for the need for stricter standards for cyanotoxins. I believe the current standards need to be more proactive. We have all seen the severe ecological and human-health impacts of cyanobacteria and the toxins it releases into our waters and air.

1. The minimum threshold for public safety concern should be the EPA's draft recommendations for Microcystins and Cylindrospermopsin. The limits of 4 ug/L for microcystins and 8 ug/L for cylindrospermopsin are appropriately protective and are more consistent with other states.

2. The estimates of exposure should not be limited to ingestion. Skin contact is another exposure method, and recently cyanobacteria has been shown to release airborne toxins, according to research from Florida Gulf Coast University. In addition, research is being conducted to find out if there is a link between ongoing exposure to microcystin and certain forms of cancer and neurological disease. EPA's final recommended values do not adequately account for multiple exposure pathways, which should be taken into consideration when setting health-based criteria.

3. The Harmful Algal Bloom Task Force, created by Governor Ron DeSantis, also recommended: "Defensible health advisories should be established by the Department of Health and defensible water quality criteria should be established by the Department of Environmental Protection."

For these reasons, and my personal desire to help save the waters & wildlife in the state where I was born & raised; I believe the water quality standards review should be revised to include stricter standards for cyanotoxins.

Sincerely,  
Rebecca D. Rodriguez

Dear Environmental Specialist Kaitlyn Sutton,

Please set water quality standards for blue green algae as part of the triennial review process. The health of citizens and wildlife are at risk.

Thank you,

Sincerely,  
Mrs Carole Tebay

**Subject:** Clean water in the St Lucie River  
**Date:** Thursday, November 21, 2019 4:09:41 PM

---

Florida Dept of Environmental Protection

It is imperative that we clean the waters of the St Lucie estuary, particularly the south fork of the river which is the flow way from the C-44 to the St Lucie Inlet. This part of the the rive is directly down wind of Bessey Creek Elementary School. We all know that the pathogens in the polluted water become airborne with any kind of southeast (prevailing) wind. There is no telling how much of these toxic materials are being ingested by our children. In the years to come, I'm sure the results of this irresponsible behavior will come home to roost as these children mature and find they are plagued by breathing difficulties and cancers of the liver, etc.

The waters from the cesspool that Lake Okeechobee has become must be stopped.

Dear Ms. Sutton,

I am contacting you because I believe we need stricter standards for cyanotoxins. The current standards need to be more strict. The ecological and human-health impacts of cyanobacteria and the toxins it releases into our waters and air are evident and we must act as such.

1. The minimum threshold for public safety concern should be the EPA's draft recommendations for Microcystins and Cylindrospermopsin. The limits of 4 ug/L for microcystins and 8 ug/L for cylindrospermopsin are appropriately protective and are more consistent with other states.

2. The estimates of exposure should not be limited to ingestion. Skin contact is another exposure method, and recently cyanobacteria has been shown to release airborne toxins, according to research from Florida Gulf Coast University. In addition, research is being conducted to find out if there is a link between ongoing exposure to microcystin and certain forms of cancer and neurological disease. EPA's final recommended values do not adequately account for multiple exposure pathways, which should be taken into consideration when setting health-based criteria.

3. The Harmful Algal Bloom Task Force, created by Governor Ron DeSantis, also recommended: "Defensible health advisories should be established by the Department of Health and defensible water quality criteria should be established by the Department of Environmental Protection."

For these reasons, and more, I believe the water quality standards review should be revised to include stricter standards for cyanotoxins.

Sincerely,

Andrea Andersen

Hello Kaitlyn, my name is Destini I come from a generation of Floridians that founded multiple towns in Florida. As a native Floridian, local business owner and lover of this environment I am speaking up in concern for the need for stricter standards for cyanotoxins. I believe the current standards need to be more proactive. We have all seen the severe ecological and human-health impacts of cyanobacteria and the toxins it releases into our waters and air. Besides the environmental and health issues that the lack of standards has created, as a business owner I have seen the economic changes within our community these past few years due to the environment.

1. The minimum threshold for public safety concern should be the EPA's draft recommendations for Microcystins and Cylindrospermopsin. The limits of 4 ug/L for microcystins and 8 ug/L for cylindrospermopsin are appropriately protective and are more consistent with other states.
2. The estimates of exposure should not be limited to ingestion. Skin contact is another exposure method, and recently cyanobacteria has been shown to release airborne toxins, according to research from Florida Gulf Coast University. In addition, research is being conducted to find out if there is a link between ongoing exposure to microcystin and certain forms of cancer and neurological disease. EPA's final recommended values do not adequately account for multiple exposure pathways, which should be taken into consideration when setting health-based criteria.
3. The Harmful Algal Bloom Task Force, created by Governor Ron DeSantis, also recommended: "Defensible health advisories should be established by the Department of Health and defensible water quality criteria should be established by the Department of Environmental Protection."

In Gratitude,  
Destini

**We need YOU to speak up for stronger water quality standards in Florida.**

*Harmful Algal Blooms (HAB) have, unfortunately, become regular and recurring events in Florida. Cyanobacteria (sometimes called blue-green algae) releases toxic microcystins, which are harmful to both humans, animals, and marine life.*

Florida's Department of Environmental Protection conducts a "Triennial Review of Water Quality Standards" every three years. This 3-year review is wrapping up **now** and **the DEP has proposed inadequate standards for these toxins.**

We need YOU to speak up in favor of more stringent standards for microcystin and cylindrospermopsin to protect human health. To read a letter of concern signed by nine different conservation organizations — including Surfrider — [click here](#). To read more about the Triennial Review, [click here](#).

**Subject:** Cyanotoxin Levels in Our Water  
**Date:** Monday, November 18, 2019 8:16:25 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Water impacts the livelihoods of countless Floridians and the lives of all Floridians. The importance of safe water cannot be overstated. Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Rebecca Weber  
Tampa, FL 33629

Dear Florida Department of Environmental Protection,

I used to live just a mile or two from the Caloosahatchee River, in the small town of Alva, and I often witnessed the disgusting neon-green algae blooms that infested the waters.

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

Dear Florida Department of Environmental Protection,

I'm writing to let you know that as a native Floridian, I am astounded at the lack of scientific standards and recovery of and for Florida's waters. My family hasn't been to a beach in 3 years, we didn't go scalloping this year, our state is suffering and the inaction is causing irreparable harm to not just the environment but to our communities and families. Fix this, enforce clean water standards, improve them, use SCIENCE to test and measure the inputs and outputs. Heal or state.

I urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. ## FWC invites anglers to TrophyCatch Hall of Fame Ceremony

The Florida Fish and Wildlife Conservation Commission (FWC) is inviting anglers and others interested in conservation to its TrophyCatch program's annual Hall of Fame Ceremony. The event will recognize the 11 anglers who caught and released largemouth bass weighing over 13 pounds that were submitted and approved during Season 7, which ended on Sept. 30. The ceremony will take place at Bass Pro Shops Gainesville, 2650 Bass Pro Shops Blvd., Gainesville, FL 32608 on Thursday, Nov. 21 at 7 p.m. TrophyCatch is a citizen-science conservation program for anglers who catch, document and release largemouth bass heavier than 8 pounds throughout Florida. The primary goal is to collect data about trophy bass to help the FWC better enhance, conserve and promote trophy bass fishing.

A key feature of TrophyCatch is prizing from industry partners to incentivize participation, and event host Bass Pro Shops has been an avid TrophyCatch conservation partner since the program's inception in 2012. Bass Pro Shops gift cards are a staple of TrophyCatch prizing, with many participants using their cards to purchase additional fishing equipment to pursue more trophy bass. Data from catch submissions are used to guide fisheries and resource enhancement decisions, improving the conservation and management of Bass Pro Shops' namesake in Florida. The company also supports other conservation efforts and research in Florida and elsewhere.

TrophyCatch prizing is based on size, with bigger catches netting bigger rewards. Anglers who caught Hall of Fame bass weighing over 13 pounds will be rewarded at the ceremony with a replica mount of their bass from New Wave Taxidermy, a customized plaque from American Registry and a \$100 Bass Pro Shops gift card among other prizes. The Hall of Fame Champion for Season 7 is Brian Hammett who caught and released a 15 pound, 13 ounce bass from Orange Lake in Marion County.

"It is amazing to realize that each one of these largemouth bass would be the state record in more than half the country," says FWC Commissioner Gary Lester who will be attending. "Florida is the Bass Fishing Capital of the World with its many trophy bass, thousands of lakes and ponds, and miles of rivers that offer quality, year-round fishing to residents and visitors alike."

Visit [TrophyCatch.com](https://www.trophycatch.com) for more information about participating.

Dear Florida Department of Environmental Protection,

My mother has lived in Sarasota for over 20 years. I'd visit often and would always come back home wishing I could stay longer. Now when I go, she's 92 years old, I am sad. The beaches and waterways often have a stench and sometimes we see dead fish, flies, etc. As much as I enjoy going into her pool, I want to swim in the warm Gulf beaches...no more.

Pass laws that will stop the pesticides, chemicals etc from running off into waters. Florida cannot survive without clean water for swimming, fishing and drinking!

Sincerely,  
Susan Birriel  
Hollywood, FL 33026

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

Not only do the algae blooms cause health hazards, they negatively affect tourism and money. I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Joanne Johnson

**Date:** Monday, November 18, 2019 7:43:44 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Dolores Guarino

**Date:** Monday, November 18, 2019 7:26:10 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Matt Borland

**Date:** Monday, November 18, 2019 7:11:58 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Joanne Bolemon

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

**Date:** Monday, November 18, 2019 7:00:04 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Cyndi Hunt  
Tallahassee, FL 32305

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards.

My son was a scuba diver until a water-borne infection ended his diving days. At the time, we were not aware of any problems in Florida's beautiful coastal waters. But now we know a lot more.

As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Stacy Bouilland

**Date:** Monday, November 18, 2019 6:53:47 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

**Date:** Monday, November 18, 2019 6:42:49 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Steve Levine  
Leesburg, FL 34788

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

**Date:** Monday, November 18, 2019 6:37:10 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

**Subject:** Please Establish Water-quality Criteria for Cyanotoxins  
**Date:** Monday, November 18, 2019 6:23:22 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Summer Devlin  
Merritt Island, FL 32953

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Taylor Brown

**Date:** Monday, November 18, 2019 6:15:03 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Kevin McCabe

Dear Florida Department of Environmental Protection,

Lives are the most important, including the life of our precious waters.

I am writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

**Subject:** Please Establish Water-quality Criteria for Cyanotoxins  
**Date:** Monday, November 18, 2019 6:03:18 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Lisa Roman

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

**Date:** Monday, November 18, 2019 8:05:16 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you to do the right thing...we all have to breathe the same air, drink the same water and eat the same foods which are all at risk from contamination from the cyanotoxins!

I'd prefer that our Florida be known as the "Sunshine Sate" and not the "Cyanotoxin State"!

Sincerely,  
Audrey Ryan

**Subject:** Please Establish Water-quality Criteria for Cyanotoxins  
**Date:** Monday, November 18, 2019 8:13:35 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
William Ahrens

Dear Florida Department of Environmental Protection,

Dangerous algae blooms have been in the news a lot the last few years. They're very concerning and that's why I write to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. These algae blooms are a serious problem, and the cyanotoxins they produce threaten human health and wildlife. People can be exposed through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Strong action is needed. Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

---

Dear Florida Department of Environmental Protection,

For all our future generations, I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

Dear Florida Department of Environmental Protection,

I teach environmental studies and ethic at the University of Florida and am a life-long surfer and ocean lover.

I'm exceptionally frustrated at the State's failure to protect our waters, wildlife, and human health, from dangerous cyanotoxins and the algae blooms that product them.

I also used to work for California's resource agency, so I know the challenges you face. Nevertheless, it is imperative that you establish strong criteria for cyanotoxins, monitoring standards, and enforcement procedures, to halt the anthropogenic sources of these blooms..

A good start would be to adopt the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final, politically influenced version issued by the EPA earlier this year.

Please act strongly and decisively. Such action is long overdue.

People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
William Farago

**Date:** Monday, November 18, 2019 8:35:29 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
John Fernandez  
Boca Raton, FL 33496

Dear Florida Department of Environmental Protection,

I am a Florida resident and have lived here for over 20 years.

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

**Date:** Monday, November 18, 2019 8:38:15 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. Harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the Department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation.

Relying only on the visual presence of an algae bloom is inadequate. Research has found that microcystins can persist even after a bloom is no longer visible, and concentrations can be higher after the initial bloom subsides. Cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums. The highest concentrations are below the water surface.

For the good of our beautiful state today and tomorrow, our children and all who inhabit Florida, PLEASE adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model.

PLEASE take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
PAT KENT

**Date:** Monday, November 18, 2019 8:54:57 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Jacqueline Barrett

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Susan Beattie

**Date:** Monday, November 18, 2019 8:59:53 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

**Date:** Monday, November 18, 2019 9:11:38 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Bethany Aiudi

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

It is obvious something concrete must be done! This problem is sickening and killing so much. In honesty Florida should not have this problem. With animal farming and the fact these industries are not held accountable for their waste presents the opening for such a problem to begin. With the use of fertilizers in farming and the run off of fertilizers we compound the problem. The extreme use of pesticides even more compounds the problem. Then the cherry on top of this mess sundae is we have hurricanes and much rain. When foods occur the animal industry as well another industries just leave without making any safeguards much less incorporating them as industry will receive a tax exemption for their losses while the pigs and other caged animals float dead down the river to decay where ever the bodies stop in the water. Without facing loss, they in fact must pay for without help, people do not pre plan for a weather event. Taxpayers should not have to pay for industry being lazy and taking advantage of the system. We, the taxpayers, are forced to pay for all these losses plus the expense of clean up and making right the wrong industry causes our state and water. And this is only one problem. It's overwhelming!

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

I was a key Water Activist during the Tampa Bay Water Wars. I helped to educate Floridians to the dangers of over pumping from the Floridan Aquifer and taking too much water from our rivers during periods of low rainfall. One of the ways that we were able to succeed was to emphasize the potential economic impact to many of Florida's industries, especially Tourism. Algae blooms and the dangerous cyanotoxins they produce are an even greater risk to Tourism and the health of Florida residents.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Judy Williams

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Joyce Randall

Dear Florida Department of Environmental Protection,

I'm urging you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. Harmful algae blooms are a serious problem. The cyanotoxins they produce threaten the health of humans & wildlife. Exposure comes through polluted water, contaminated seafood, skin or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the base for future monitoring & help state officials when notifying the public of any danger from blooms & address factors that lead to these blooms such as nutrient pollution, insufficient water velocities, flows, levels to rising temperatures, & changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

**Date:** Monday, November 18, 2019 9:40:14 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Holly Crawford  
Orange, CA 92869

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Kelly Lyon

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

Dear Florida Department of Environmental Protection,

Since moving to Florida 2 years ago, I have been very concerned about the continuing threat of Red Tide and toxic algae blooms. I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

TAKE ACTION NOW to establish the information needed to ward off cyanotoxins produced by the algae blooms in our the state's water. We NEED water quality standards and we need them now REGARDLESS of what corporations are involved! .

All the factors must be address that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Linda Kay

**Subject:** Please Establish Water-quality Criteria for Cyanotoxins  
**Date:** Monday, November 18, 2019 10:41:08 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Teresa Salerno

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

**Date:** Monday, November 18, 2019 10:35:03 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Heather Hollopeter

**Date:** Monday, November 18, 2019 10:17:25 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Christian Camphire

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Pauline Gillham

Dear Florida Department of Environmental Protection,

Algae blooms, Gulf to bay, are making us sick. I have lived at the beach for 30+ years. The blooms multiply and intensity. They used to be a surprise; now we expect and anticipate them. Beyond monitoring and setting limits, establishing warnings, get to the root(s) of the blooms and turn this ship around.

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Melissa Gaskins

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you. I appreciate you taking the time to read and think about this. I moved to Florida 3 years ago. I used to vacation here but it wasn't until I moved that I realized how important it is that there are safety measures taken to keep everyone safe. People need and have the right to know about this. Their health is at stake. More needs to be done to keep the water clean here in my opinion. This is a step in the right direction.

Sincerely,

Dear Florida Department of Environmental Protection,

It's frightening to see what's happening to our water ways and oceans. We've lived in Florida 40 years... And we've been afraid to take our grandchildren anywhere near the waters for fear of what will happen to them. What are you doing to protect our environment and the legacy we're leaving future generations?

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

**Date:** Monday, November 18, 2019 11:20:06 AM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Alan Darpini  
Miami, FL 33176

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. I CANNOT believe that Florida hasn't already done this!!

As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Beth Merrill

Dear Florida Department of Environmental Protection,

I'm writing today to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you may know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health, our precious dogs, and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

**Subject:** Please Establish Water-quality Criteria for Cyanotoxins  
**Date:** Monday, November 18, 2019 12:20:39 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Sallye Shaddix  
Port Richey, FL 34668

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,

**Date:** Monday, November 18, 2019 12:34:00 PM

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Dear Florida Department of Environmental Protection,

Besides everything said below our water systems (fresh and salt) are a big part of our tourist industry, which affects Florida's economy. If you won't protect our water for the sake of our environment, please protect it to keep money flowing into the state.

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

---

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
Bev Hansen

Dear Florida Department of Environmental Protection,

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.

Sincerely,  
David Kutob

Dear Florida Department of Environmental Protection,

Having a weakened Immune system , and having had the experience of ICU nursing people who have been infected in "natural" Florida waters , I know and have experienced the DIRE condition of our water resources.

I'm writing to urge you to establish criteria for cyanotoxins during the triennial review of the state's water-quality standards. As you know harmful algae blooms are a serious problem, and the cyanotoxins they produce are threatening human health and wildlife. People can be exposed to them through polluted water, contaminated seafood, skin exposure or inhalation.

By establishing criteria for cyanotoxins, the Florida Department of Environmental Protection would set clear numeric baselines for our state's recreational waters, forming the basis for future monitoring and helping state officials notify the public when blooms become dangerous. The criteria would also help the department address all the factors that lead to these blooms — from nutrient pollution and insufficient water velocities, flows and levels to rising temperatures and changes in precipitation fueled by climate change.

Relying only on the visual presence of an algae bloom as a threshold for action is inadequate and doesn't follow the precautionary principle. Researchers have found, for instance, that microcystins can persist even after a bloom is no longer visible, and concentrations can actually be higher after the initial bloom subsides. They've also found that cylindrospermopsin-producing cyanobacteria don't tend to form visible surface scums, and the highest concentrations are below the water surface.

For all these reasons, I urge the state to adopt new criteria and to use the EPA's 2016 draft recommendations for microcystins and cylindrospermopsin as a model. This is the strongest, most comprehensive set of criteria put forth to date, and far more so than the final version issued by the EPA earlier this year.

Please take advantage of this tremendous opportunity and be the first state in the nation to adopt water-quality criteria for cyanotoxins. We're counting on you.
