Do the models appropriately address limited pools in soil attachment sites and increasing biomass such that within a short time those pools can no longer accrete nutrients and the only pool left is in the creation of new soil?

Rule comments Lawrence Keenan, Ph.D

Do the "standard numerical models or analytical tools" allocate nutrient removal in "phases" for nutrient removal by hydric soils that have to accumulate over time?

Do the "standard numerical models or analytical tools" include something akin to the old habitat equivalency analysis to allocate biological improvements in "phases" over time?

Will the water quality measurements be included in the main DEP database (STORET?) with a tag to show it is in a management area?
